1 Introduction

In the following paper, I will show that prime numbers can be calculated recursively. I will start with the suggestion of descriptions itself, over different perspectives on this problem, until the final explanation of caculating prime numbers in the most efficient way, as a result from this considerations.

Let's start with the definition of prime numbers itself.

Definition 1.0.1 (Prime numbers) *Every natural number greater than one which has no positive integer divisors apart from one and itself is called Prime Number or just only Prime.*

Be $\mathcal{P}$ the set of all prime numbers p. So we can write

$$\mathcal{P} := \{p \in \mathbb{N}_{>1} \mid \forall n \in \mathbb{N}_{>1} \setminus \{p\} : \; n \nmid p\}.$$

Hence, the first prime numbers are $\mathcal{P} := \{2, 3, 5, 7, 11, 13, 17, 19, 23, \dots\}$.

2 Odd-Divisible Numbers

Contents

At first, for the description of prime numbers, we have to look at the set of divisible numbers. Since, apart from 2, all prime numbers are odd, we will only analyze this numbers. In the whole paper, we will ignore the prime number 2, because we will see, this makes a lot easier.

2.1 Basic description: Odd-Numbers

Be given the set of all odd natural numbers $y \in \mathbb{N}_{>1}$ through

$$y_i\left(x_i\right) := 2x_i + 1, \tag{2.1}$$

with $x, i \in \mathbb{N}$. If we expand the definition set of x to $\mathbb{Z}$, we also know

$$\begin{aligned} y\left(0\right) &= 1 && (2.2) \\ \text{and} \quad y(-x) &= 2\left(-x\right) + 1 \\ &= -\left(2x - 1\right) \\ &= -\left(2\left(x-1\right) + 1\right) \\ &= -y\left(x-1\right). && (2.3) \end{aligned}$$

Later, we will see that this properties can be very useful.

2.2 Basic description: Odd-Divisible Numbers

Next, we look at all odd-divisible numbers. We know, they can't have a factor which is a multiple of 2. Hence, we get an equation which describes all odd-divisible numbers by

$$\begin{aligned} y_{i,j}\left(x_i, x_j\right) &= y_i\left(x_i\right) \cdot y_j\left(x_j\right) \\ &= \left(2x_i + 1\right)\left(2x_j + 1\right) \\ &= 2^2 x_i x_j + 2x_i + 2x_j + 1 \\ &= 2\left(\underbrace{2x_i x_j + x_i + x_j}_{=:x_{i,j}}\right) + 1 \\ &= y_{i,j}\left(x_{i,j}\right). \end{aligned} \tag{2.4}$$

If we expand again our sets to $\mathbb{Z}$, we receive additional cases. At first, assume at one factor is $y(0) = 1$. We see directly

$$\begin{aligned} y_{0,j}\left(0, x_j\right) &= y_0(0) \cdot y_j\left(x_j\right) \\ &= 1 \cdot \left(2x_j + 1\right) \\ &= 2x_j + 1 \\ &= y_j\left(x_j\right) \end{aligned} \tag{2.5}$$

$$\text{respectively} \quad y_{i,0}\left(x_i, 0\right) = y_i\left(x_i\right). \tag{2.6}$$

Next, assume we have one factor with $y(-x)$.

$$\begin{aligned} y_{i,j}\left(-x_i, x_j\right) &= y_i\left(-x_i\right) \cdot y_j\left(x_j\right) \\ &= \left(2\left(-x_i\right) + 1\right)\left(2x_j + 1\right) \\ &= -2^2 x_i x_j - 2x_i + 2x_j + 1 \\ &= -\left(2\left(2x_i x_j + x_i - x_j - 1\right) + 1\right) \\ &= -\left(2\left(2x_i x_j + x_i - 2x_j + x_j - 1\right) + 1\right) \\ &= -\left(2\left(2\left(x_i - 1\right) x_j + \left(x_i - 1\right) + x_j\right) + 1\right) \\ &= -y_i\left(x_i - 1\right) \cdot y_j\left(x_j\right) \end{aligned} \tag{2.7}$$

$$\text{respectively} \quad y_{i,j}\left(x_i, -x_j\right) = -y_i\left(x_i\right) \cdot y_j\left(x_j - 1\right) \tag{2.8}$$

In the case of two negative factors, we have

$$\begin{aligned}
y_{i,j}(-x_i, -x_j) &= y_i(-x_i) \cdot y_j(-x_j) \\
&= (2(-x_i) + 1)(2(-x_j) + 1) \\
&= (2x_i - 1)(2x_j - 1) \\
&= 2^2 x_i x_j - 2x_i - 2x_j + 1 \\
&= 2(2x_i x_j - x_i - x_j) + 1 \\
&= (2x_i - 2 + 1)(2x_j - 2 + 1) \\
&= (2(x_i - 1) + 1)(2(x_j - 1) + 1) \\
&= (-1)\, y_i(x_i - 1)(-1)\, y_j(x_j - 1) \\
&= (-1)^2\, y_{i,j}(x_i - 1, x_j - 1)\,. \qquad (2.9)
\end{aligned}$$

2.3 Odd-Divisible Numbers: Different perspectives

Finally, we see the different possible perspectives for odd-divisible numbers.

$$\begin{aligned}
y_{i,j}(x_i, x_j) &= 2(2x_i x_j + x_i + x_j) + 1 \\
&= 2((2x_i + 1)\, x_j + x_i) + 1 \qquad (2.10) \\
\text{respectively} \quad &= 2((2x_j + 1)\, x_i + x_j) + 1 \qquad (2.11)
\end{aligned}$$

We will use (2.10) respectively (2.11) in the next step, for the description of odd numbers which are not divisible by a particular other odd number.

3 Odd-Not-Divisible Numbers

Contents

After we spent time with the set of all odd-divisible numbers, now, we switch to the set of all odd numbers which are not divisible by a particular other odd number.

3.1 Representation: Odd-Divisible Numbers

Let's look again at (2.10)

$$y_{i,j}\left(x_i, x_j\right) = 2\left(\left(2x_i + 1\right)x_j + x_i\right) + 1,$$

and its belonging values.

- Be $x_i = 1$:
$$y_{1,j}\left(1, x_j\right) = 2\left(3x_j + 1\right) + 1, \quad x_{1,j} = 3x_j + 1 \tag{3.1}$$

Table 3.1: The first ten values for (3.1).

x_j	1	2	3	4	5	6	7	8	9	10
$x_{1,j}$	4	7	10	13	16	19	22	25	28	31
$y_{1,j}$	9	15	21	27	33	39	45	51	57	63

- Be $x_i = 2$:
$$y_{2,j}\left(2, x_j\right) = 2\left(5x_j + 2\right) + 1, \quad x_{2,j} = 5x_j + 2 \tag{3.2}$$

Table 3.2: The first ten values for (3.2).

x_j	1	2	3	4	5	6	7	8	9	10
$x_{2,j}$	7	12	17	23	28	33	38	43	48	53
$y_{2,j}$	15	25	35	47	57	67	77	87	97	107

- Be $x_i = 3$:

$$y_{3,j}\left(3, x_j\right) = 2\left(7x_j + 3\right) + 1, \quad x_{3,j} = 7x_j + 3 \tag{3.3}$$

Table 3.3: The first ten values for (3.3).

x_j	1	2	3	4	5	6	7	8	9	10
$x_{3,j}$	10	17	24	31	38	45	52	59	66	73
$y_{3,j}$	21	35	49	63	77	91	105	119	133	147

- Be $x_i = \ldots$: ....

3.2 Representation: Odd-Not-Divisible Numbers

Now, we take again $y_{i,j}\left(x_i, x_j\right) = 2\left(\left(2x_i + 1\right)x_j + x_i\right) + 1$ and rephrase it into an equation which descripes all odd numbers which are not divisible by $2x_i + 1$.
That's not very hard. We can write

$$y_{i,j}\left(x_i, x_j\right) = 2\left(\left(2x_i + 1\right)x_j + x_i - \mu\left(x_i\right)\right) + 1, \tag{3.4}$$

with

$$\mu\left(x_i\right) = 1, \ldots, 2x_i, \quad \mu\left(x_i\right) \in \mathbb{N}. \tag{3.5}$$

Let's have a short look at the first values for $x_i = 1, 2, 3$.

- Be $x_i = 1$:

$$y_{1,j}\left(1, x_j\right) = 2\left(3x_j + 1 - \mu\left(1\right)\right) + 1, \quad \mu\left(1\right) = 1, 2, \quad x_{1,j} = 3x_j + 1 \tag{3.6}$$

Table 3.4: The first values for (3.6).

x_j	1		2		3		4		5	
$\mu(1)$	1	2	1	2	1	2	1	2	1	2
$x_{1,j}$	2	3	5	6	8	9	11	12	14	15
$y_{1,j}$	5	7	11	13	17	19	23	25	29	31

- Be $x_i = 2$:

$$y_{2,j}\left(2, x_j\right) = 2\left(5x_j + 2 - \mu\left(2\right)\right) + 1, \quad \mu\left(2\right) = 1, \ldots, 4 \quad x_{2,j} = 5x_j + 1 \tag{3.7}$$

Table 3.5: The first values for (3.7).

x_j	1				2				3	
$\mu(1)$	1	2	3	4	1	2	3	4	1	2
$x_{2,j}$	3	4	5	6	8	9	10	11	13	14
$y_{2,j}$	7	9	11	13	17	19	21	23	27	29

- Be $x_i = 3$:

$$y_{3,j}\left(3, x_j\right) = 2\left(7x_j + 1 - \mu\left(3\right)\right) + 1, \quad \mu\left(3\right) = 1, \ldots, 6 \quad x_{3,j} = 7x_j + 1 \tag{3.8}$$

Table 3.6: The first values for (3.8).

x_j	1						1			
$\mu\left(1\right)$	1	2	3	4	5	6	1	2	3	4
$x_{3,j}$	4	5	6	7	8	9	11	12	13	14
$y_{3,j}$	9	11	13	15	17	19	23	25	17	29

- Be $x_i = \ldots$: ...

Remark 3.2.1 (Value set) *You can see, the valid value set start not till* $x_{i,j} = x_i + 1$*.*

3.3 Odd-Not-Divisible Numbers: Intersection

Now we look at the intersection of two equations of the type (3.4) with (3.5). Hence, we start with

$$\begin{aligned} y_{i,j}^{(1)}\left(x_i^{(1)}, x_j^{(1)}\right) &= 2\left(\left(2x_i^{(1)} + 1\right)x_j^{(1)} + x_i^{(1)} - \mu\left(x_i^{(1)}\right)\right) + 1 \\ \mu\left(x_i^{(1)}\right) &= 1, \ldots, 2x_i^{(1)} \qquad (3.9) \\ \text{and} \quad y_{i,j}^{(2)}\left(x_i^{(2)}, x_j^{(2)}\right) &= 2\left(\left(2x_i^{(2)} + 1\right)x_j^{(2)} + x_i^{(2)} - \mu\left(x_i^{(2)}\right)\right) + 1 \\ \mu\left(x_i^{(2)}\right) &= 1, \ldots, 2x_i^{(2)}. \qquad (3.10) \end{aligned}$$

We do the intersection:

$$\begin{aligned} 0 &= \left(2x_i^{(1)} + 1\right)x_j^{(1)} - \left(2x_i^{(2)} + 1\right)x_j^{(2)} + x_i^{(1)} - x_i^{(2)} - \mu\left(x_i^{(1)}\right) + \mu\left(x_i^{(2)}\right) \qquad (3.11) \\ \Leftrightarrow \quad 0 &= \left(2x_i^{(1)} + 1\right)\left(x_j^{(1)} - x_j^{(2)}\right) - \left(2x_j^{(2)} + 1\right)\Delta x_i^{(1,2)} - \mu\left(x_i^{(1)}\right) + \mu\left(x_i^{(2)}\right) \qquad (3.12) \end{aligned}$$

For the second one, we used $x_i^{(2)} = x_i^{(1)} + \Delta x_i^{(1,2)}$, $x_i^{(2)} > x_i^{(1)}$ and $\Delta x_i^{(1,2)} \in \mathbb{N}$.
To solve (3.11) respectively (3.12), we recognize that we have the boundary condition, that $\left(2x_i^{(1)} + 1\right)$ and $\left(2x_i^{(2)} + 1\right)$ must not have any common factors.

4 The recursive calculation

Contents

In this section, now, we do the final recursive calculation. To understand the deep structure we will do this by discussing the first steps by manually calculation.

4.1 Recursion step: $n^{(1)} = 1$

We start our calculation with an easy consideration.
